1 Summary

TFDWT is an open-source Python package that allows the creation of TensorFlow Layers for Fast Discrete Wavelet Transform (DWT) and Inverse Discrete Wavelet Transform (IDWT) in end-to-end backpropagation learning networks. These layers facilitate the construction of multilevel DWT filterbanks and Wavelet Packet Transform (WPT) filterbanks for a spatial-frequency representation of the inputs and features in shallow or deep networks. A multiresolution signal representation using a multi-rate discrete wavelet system creates enriched joint natural-frequency representations. The discrete wavelet system partitions the frequency plane into subbands using orthogonal dilated and translated lowpass scaling and highpass wavelet function. A realization of a fast discrete wavelet system is a two-band perfect reconstruction multi-rate filter bank with FIR filters corresponding to the impulse responses of the scaling and wavelet function with downsampling and upsampling operations. A filter bank for a higher dimensional input is a seamless extension by successive separable circular convolutions across each independent axis.

2 Statement of need

In machine or deep learning, an efficient multiresolution representation of data often helps to build economical and explainable models. The Wavelet toolbox (Misiti et al., 1996) by MathWorks is a proprietary software that has served the requirements for D-dimensional wavelet transforms in the MATLAB environment for a few decades. Several open-source packages are now available for 1D and 2D DWT in Python. Pywavelets (Lee et al., 2019) is a D-dimensional wavelet transform library in Python that works with Numpy (Harris et al., 2020) arrays. However, it is challenging to directly use Pywavelets with the symbolic tensors in TensorFlow (Developers, 2022) layers and CUDA (Fatica, 2008). WaveTF (Versaci, 2021) is a solution for constructing 1D and 2D DWT layers in TensorFlow but is limited to only Haar and Db2 wavelets. The package tensorflow-wavelets (Leiderman, 2025) supports multiple wavelets, but it has a minor bug in perfect reconstruction due to the padding and boundary effects in processing the finite-length inputs. In Pytorch (Imambi et al., 2021), the pytorch-wavelets (Cotter, 2023) package allows the construction of 1D and 2D DWT layers. However, there are limited libraries for 3D and higher transforms with a wide range of wavelet families for Graphics Processing Unit (GPU) computations.

For a D-dimensional wavelet $\psi \in L^2(\mathbb{R})^D$, a discrete wavelet system defined by $\{\psi_{m,p} : m \in \mathbb{Z}, p \in \mathbb{Z}^D\}$ forms an orthonormal basis in $\psi \in L^2(\mathbb{R})^D$, where $\psi_{m,p}(x) := 2^m \psi(2^m x - p)$. Then, by definition the DWT of $x \in \mathbb{Z}^D$ is $x \mapsto (\langle x, \psi_{m,p} \rangle)_{m,p}$, where m is the dilation parameter and p is the shift or translation parameter. The TFDWT Python package is a simple standalone DWT and IDWT library with minimal dependencies that allow computation with symbolic tensors and CUDA. This release supports up to 3D forward and inverse transforms with various orthogonal and biorthogonal wavelet families. A seamless package upgrade for higher

dimensional DWT is possible by separable transforms. The boundary effects are taken care of with cyclic convolutions instead of padding. The package supports orthogonal and biorthogonal wavelets of different families having impulse responses of diverse lengths. In this paper, we defined the platform-independent, underlying mathematics for realizing fast DWT and IDWT layers with filter bank structures having FIR filters, downsamplers and upsamplers. Although our realization of the discrete wavelet system is in TensorFlow 2, a seamless reproduction of the computations is possible in other deep learning frameworks.

3 Discrete wavelet system for sequences

A discrete wavelet system has a lowpass scaling function and a highpass wavelet. The realization of a discrete wavelet system with a continuous one-dimensional ($D=1$) mother wavelet $\psi \in L^2(\mathbb{R})$ is by using the impulse responses of the scaling function and the wavelet as Finite Impulse Response (FIR) filters $g[n]$ and $h[n]$. Figure 1 shows wavelets and scaling functions of the analysis and synthesis bank of bior3.1 wavelet and their corresponding impulse responses are shown in Figure 2. These FIR filters are the building blocks of a two-band perfect reconstruction filter bank for realizing fast discrete wavelet systems. Figure 3 shows a two-band perfect reconstruction filter bank that operates on one-dimensional inputs, i.e., sequences in $l^2(\mathbb{Z})$. The analysis and synthesis bank in orthogonal wavelet systems have identical lowpass and highpass FIR filters but differ in biorthogonal wavelet systems. In biorthogonal wavelet filter banks, $\tilde{g}[n]$ and $\tilde{h}[n]$ are the lowpass and highpass filters of the synthesis bank. The only difference in the biorthogonal families like bior and rbio is the interchange of the analysis and synthesis scaling and wavelets functions, for example, in bior3.1 and rbio3.1.

Figure 1: Wavelets and scaling functions of bior3.1 analysis (left) and synthesis (right).

Figure 2: Impulse responses of different bior3.1 analysis (left two) and synthesis (right two) lowpass and highpass FIR filters.

3.1 Circular convolution operators

The four matrices in the two band perfect reconstruction filter bank in Figure 3 are — (i) G is lowpass analysis matrix, (ii) H is highpass analysis matrix, (iii) \tilde{G} is lowpass synthesis matrix and (iv) \tilde{H} is highpass synthesis matrix. These matrices are operators for circular convolution, constructed by circular shifts of the corresponding FIR filters $g[n-k]$, $h[n-k]$, $\tilde{g}[n-k]$ and $\tilde{h}[n-k]$, where $g = \tilde{g}$ and $h = \tilde{h}$ for orthogonal wavelets.

Figure 3: Two band perfect reconstruction filter bank.

3.1.1 Analysis matrix

For a lowpass analysis FIR filter of length L and a input sequence of length N , the circular convolution operator is a matrix G of shape $N \times N$. A downsampling by two $f_{(\downarrow 2)}$ of the output the convolution is equivalent to getting rid of the even rows of G to give $\frac{N}{2} \times N$ operator $f_{(\downarrow 2)}G$. Similarly, for the highpass analysis FIR filter of same wavelet with convolution and downsampling is a $\frac{N}{2} \times N$ operator $f_{(\downarrow 2)}H$. The analysis matrix is,

$$A = \begin{bmatrix} f_{(\downarrow 2)}G \\ f_{(\downarrow 2)}H \end{bmatrix}_{N \times N}$$

where A is a $N \times N$ decimated circular convolution operator formed by combining the lowpass and highpass decimated operators].

3.1.2 Synthesis matrix

The synthesis matrix S is another $N \times N$ decimated circular convolution operator as given by equation [eq:SynthesisMatrix],

$$S = \begin{bmatrix} f_{(\downarrow 2)}\tilde{G} \\ f_{(\downarrow 2)}\tilde{H} \end{bmatrix}_{N \times N}^T$$

where \tilde{G} and \tilde{H} are matrices formed by the lowpass and highpass synthesis FIR filters. The above is a general representation for both orthogonal and biorthogonal wavelets families where for orthogonal wavelets, $\tilde{G} = G$, $\tilde{H} = H$ and thus $S = A^T$.

A two-band perfect reconstruction discrete wavelet system for one-dimensional inputs is given by the analysis equation and the synthesis equation,

$$q = \text{DWT}(x) \text{ or, } q = (Ax^T)^T \text{—Analysis}$$

$$x = \text{IDWT}(q) \text{ or, } x = (Sq^T)^T \text{—Synthesis}$$

where A and S are analysis and synthesis matrices, x is a input sequence and q has a distinct lowpass and a highpass subband.

Example 1. Given, a sequence $x \in \mathbb{R}^8$ or $N = 8$ and FIR filters length $L = 6$.

$$\text{LPF and downsampling } f_{(\downarrow 2)}G = \begin{bmatrix} g_1 & g_0 & 0 & 0 & g_5 & g_4 & g_3 & g_2 \\ g_3 & g_2 & g_1 & g_0 & 0 & 0 & g_5 & g_4 \\ g_5 & g_4 & g_3 & g_2 & g_1 & g_0 & 0 & 0 \\ 0 & 0 & g_5 & g_4 & g_3 & g_2 & g_1 & g_0 \end{bmatrix}_{\frac{N}{2} \times N}$$

$$\text{HPF and downsampling } f_{(\downarrow 2)} \mathbf{H} = \begin{bmatrix} h_1 & h_0 & 0 & 0 & h_5 & h_4 & h_3 & h_2 \\ h_3 & h_2 & h_1 & h_0 & 0 & 0 & h_5 & h_4 \\ h_5 & h_4 & h_3 & h_2 & h_1 & h_0 & 0 & 0 \\ 0 & 0 & h_5 & h_4 & h_3 & h_2 & h_1 & h_0 \end{bmatrix}_{\frac{N}{2} \times N}$$

$$\text{Analysis matrix is } \mathbf{A} = \begin{bmatrix} g_1 & g_0 & 0 & 0 & g_5 & g_4 & g_3 & g_2 \\ g_3 & g_2 & g_1 & g_0 & 0 & 0 & g_5 & g_4 \\ g_5 & g_4 & g_3 & g_2 & g_1 & g_0 & 0 & 0 \\ 0 & 0 & g_5 & g_4 & g_3 & g_2 & g_1 & g_0 \\ h_1 & h_0 & 0 & 0 & h_5 & h_4 & h_3 & h_2 \\ h_3 & h_2 & h_1 & h_0 & 0 & 0 & h_5 & h_4 \\ h_5 & h_4 & h_3 & h_2 & h_1 & h_0 & 0 & 0 \\ 0 & 0 & h_5 & h_4 & h_3 & h_2 & h_1 & h_0 \end{bmatrix}_{N \times N}$$

89 Similarly,

$$\text{Synthesis matrix is } \mathbf{S} = \begin{bmatrix} \tilde{g}_1 & \tilde{g}_0 & 0 & 0 & \tilde{g}_5 & \tilde{g}_4 & \tilde{g}_3 & \tilde{g}_2 \\ \tilde{g}_3 & \tilde{g}_2 & \tilde{g}_1 & \tilde{g}_0 & 0 & 0 & \tilde{g}_5 & \tilde{g}_4 \\ \tilde{g}_5 & \tilde{g}_4 & \tilde{g}_3 & \tilde{g}_2 & \tilde{g}_1 & \tilde{g}_0 & 0 & 0 \\ 0 & 0 & \tilde{g}_5 & \tilde{g}_4 & \tilde{g}_3 & \tilde{g}_2 & \tilde{g}_1 & \tilde{g}_0 \\ \tilde{h}_1 & \tilde{h}_0 & 0 & 0 & \tilde{h}_5 & \tilde{h}_4 & \tilde{h}_3 & \tilde{h}_2 \\ \tilde{h}_3 & \tilde{h}_2 & \tilde{h}_1 & \tilde{h}_0 & 0 & 0 & \tilde{h}_5 & \tilde{h}_4 \\ \tilde{h}_5 & \tilde{h}_4 & \tilde{h}_3 & \tilde{h}_2 & \tilde{h}_1 & \tilde{h}_0 & 0 & 0 \\ 0 & 0 & \tilde{h}_5 & \tilde{h}_4 & \tilde{h}_3 & \tilde{h}_2 & \tilde{h}_1 & \tilde{h}_0 \end{bmatrix}_{N \times N}$$

90 The DWT of x produces subbands,

$$\mathbf{q} = \text{DWT}(x) \text{ or, } \mathbf{q} = \mathbf{A}x$$

91 Perfect reconstruction,

$$x = \text{IDWT}(\mathbf{q}) \text{ or, } x = \mathbf{S}q$$

92 3.2 DWT 1D layer

93 A DWT 1D layer takes batched, multichannel sequences of shape (batch, length, channels) as
94 input and computes subbands of each sequence using equation [eq:DWToneSequence]. The
95 shape of the DWT 1D layer output after grouping the lowpass and highpass subbands of each
96 sequence is (batch, length/2, 2 × channels).

97 Algorithm 1a

- 98 1. Input \mathbf{X} of shape (batch, length, channels).
- 99 2. Generate analysis matrix \mathbf{A} using length of input.
- 100 3. For each batched channel $x_c \in \mathbf{X}$ of shape (batch, length):
101 (omitting suffix c in x below for simplicity of notation)
102 Batch DWT 1D: $q_c = \mathbf{A}x_c^T$
- 103 4. Stacking for all c channels: $\mathbf{Q} := (q_c)_{\forall c}$ to a shape (batch, length, channels).
- 104 5. Group subbands and return an output $\mathbf{Q}^{(\text{grouped})}$ of shape (batch, length/2, 2 × channels)

```
# Grouping two subbands in DWT 1D
mid = int(Q.shape[1]/2)
L = Q[:, :mid, :]
H = Q[:, mid:, :]
out = Concatenate([L, H], axis=-1)
```

105 3.3 IDWT 1D layer

106 An IDWT 1D layer takes batched, multichannel subbands of shape (batch, length/2, $2 \times$
107 channels). as input and reconstructs each batched, multichannel sequence using equation
108 [eq:IDWToneSequence]. The shape of the IDWT 1D layer output is (batch, length, channels).

109 Algorithm 1b

- 110 1. Input $Q^{(\text{grouped})}$ of shape (batch, length/2, $2 \times$ channels)
- 111 2. Ungroup the subbands to get Q of shape (batch, length, channels)
- 112 3. Generate synthesis matrix S using length of Q .
- 113 4. For each batched channel $q_c \in Q$ of shape (batch, length):
114 (omitting suffix c in q below for simplicity of notation)
 - 115 ■ Batched IDWT 1D: $x = Sq^T$, i.e., a perfect reconstruction, where, $S = A^T$ for
116 orthogonal wavelets
- 117 5. Layer output (perfect reconstruction): $X := (x_c)_{\forall c}$ is of shape (batch, length, channels)

118 4 Higher dimensional discrete wavelet systems

119 In sequences (1D), the DWT 1D applies to the only independent variable. To achieve high-
120 dimensional DWT, the DWT 1D needs to be applied separately to all the independent variables
121 one after the other. For example, the DWT of an image (2D) is a row-wise DWT 1D followed
122 by a column-wise DWT 1D. Similarly, the reconstruction is column-wise IDWT 1D followed by
123 a row-wise IDWT 1D.

124 4.1 Two-dimensional discrete wavelet system

125 The pixel values in an image are a function of two independent spatial axes. A DWT 2D filter
126 bank is a separable transform with row-wise filtering followed by column-wise filtering that
127 yields four subbands - LL, LH, HL and HH. A two-dimensional discrete wavelet system is given
128 by,

$$q = \text{DWT}(x) := A(Ax_{021})_{021}^T \quad \text{—Analysis}$$

$$x = \text{IDWT}(q) := S(S[A(Ax_{021}^T)_{021}^T]_{021}^T)^T \quad \text{—Synthesis}$$

129 where, A and S are the same analysis and synthesis matrices defined for one-dimensional
130 wavelet system. Figure 4 shows an $N \times N$ image and its four localized spatial-frequency
131 subbands after DWT. Here, the low-frequency band is LL, and the other three are high-
132 frequency subbands representing horizontal, vertical and diagonal features. Figure 5 illustrates
133 a separable 2D DWT perfect reconstruction filter bank. The 2D layers operate on batched,
134 multichannel tensors of shape (batch, height, width, channels), where each image is of shape
135 height and width. Figure 6 illustrates input, output and perfect reconstruction by DWT 2D
136 and IDWT 2D layers. The Multiresolution Encoder-Decoder Convolutional Neural Network in
137 (Tarafdar et al., 2025) uses these layers.

Figure 4: An image of shape (left) and spatial-frequency tiled subbands (right) after a level-1 DWT 2D decomposition.

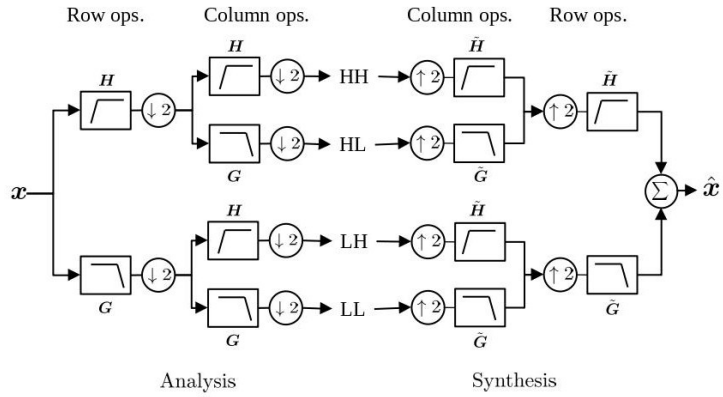

Figure 5: Separable DWT 2D perfect reconstruction filter bank.

4.1.1 DWT 2D layer

A DWT 2D layer operates on input tensors of shape (batch, height, width, channels) and produces an output of shape (batch, height/2, width/2, 4 × channels) as described in Algorithm 2a.

Algorithm 2a

1. Input \mathbf{X} of shape (batch, height, width, channels).
 2. Generate analysis matrix \mathbf{A} using height and width of input.
 3. For each batched channel $\mathbf{x}_c \in \mathbf{X}$ of shape (batch, height, width):
(omitting suffix c in \mathbf{x} below for simplicity of notation)
 1. Row-wise batch DWT 1D: $\mathbf{A}\mathbf{x}_{021}^T := \text{Einsum}(ij, bjk \rightarrow bik)$
 2. Column-wise batch DWT 1D: $\mathbf{A}(\mathbf{A}\mathbf{x}_{021}^T)_{021}^T := \text{Einsum}(ij, bjk \rightarrow bik)$
- Or, equivalently, DWT of a batched channel \mathbf{x} is,

$$\mathbf{q}_c = \text{DWT}(\mathbf{x}) \text{ or } \mathbf{q}_c = \mathbf{A}(\mathbf{A}\mathbf{x}_{021})_{021}^T$$

4. Stacking for all c channels: $\mathbf{Q} := (\mathbf{q}_c)_{\forall c}$ to a shape (batch, height, width, channels).
5. Group subbands and return an output $\mathbf{Q}^{(\text{grouped})}$ of shape (batch, height/2, width/2, 4 × channels)

```
# Grouping four subbands in DWT 2D
mid = int(Q.shape[1]/2)
```

```
LL = Q[:, :mid, :mid, :]
LH = Q[:, mid:, :mid, :]
HL = Q[:, :mid, mid:, :]
HH = Q[:, mid, mid:, :]
output = Concatenate([LL, LH, HL, HH], axis=-1)
```

153 4.1.2 IDWT 2D layer

154 An IDWT 2D layer operates on input tensors of shape (batch, height/2, width/2, $4 \times$ channels)
155 and produces an output of shape (batch, height, width, channels) as described in Algorithm
156 2b.

157 Algorithm 2b

- 158 1. Input $Q^{(\text{grouped})}$ of shape (batch, height/2, width/2, $4 \times$ channels)
- 159 2. Ungroup the subbands to get Q of shape (batch, height, width, channels)
- 160 3. Generate synthesis matrix S using height and width of Q .
- 161 4. For each batched channel $q_c \in Q$ of shape (batch, height, width):
162 (omitting suffix c in q below for simplicity of notation)
 - 163 1. Row-wise batch IDWT 1D: $Sq_{021}^T := \text{Einsum}(ij, bjk \rightarrow bik)$
 - 164 2. Column wise batch IDWT 1D: $S(Sq_{021}^T)_{021}^T := \text{Einsum}(ij, bjk \rightarrow bik)$
 - 165 or equivalently, a perfect reconstruction,
$$x = \text{IDWT}(q) \text{ or } x = S(Sq_{021}^T)_{021}^T$$
- 166 where, $S = A^T$ for orthogonal wavelets
- 167 5. Layer output (perfect reconstruction): $X := (x_c)_{\forall c}$ is of shape (batch, height, width, channels)

Figure 6: DWT decomposition and perfect reconstruction of a tensor , where is DWT 2D layer and is IDWT 2D layer.

168 4.2 Three-dimensional discrete wavelet system

169 A three-dimensional (3D) discrete wavelet system for a 3D input x is given by,

$$q = \text{DWT}(x) := [A(A(Ax_{0213}^T)_{0213}^T)_{0132}^T]_{0132}^T \quad \text{—Analysis}$$

$$x = \text{IDWT}(q) := (S(S(S[A(A(Ax_{0213}^T)_{0213}^T)_{0132}^T]_{0132}^T)_{0132}^T)_{0213}^T)_{0213}^T \quad \text{—Synthesis}$$

170 where, A and S are the same analysis and synthesis matrices as defined for one-dimensional
171 wavelet system. The DWT 3D and IDWT 3D layers operate on batched, multichannel tensors
172 of shape (batch, height, width, depth, channels).

173 4.2.1 DWT 3D layer

174 A DWT 3D layer operates on input tensors of shape (batch, height, width, depth, channels)
175 and produces an output of shape (batch, height/2, width/2, depth/2, $8 \times \text{channels}$) as described
176 in Algorithm 3a.

177 Algorithm 3a

- 178 1. Input X of shape (batch, height, width, depth, channels).
- 179 2. Generate analysis matrix A using height, width and depth of input.
- 180 3. For each batched channel $x_c \in X$ of shape (batch, height, width, depth):
181 (omitting suffix c in x below for simplicity of notation)
 - 182 1. Row-wise batch DWT 1D: $Ax_{0213}^T := \text{Einsum}(ij, b j k l \rightarrow b i k l)$
 - 183 2. Column-wise batch DWT 1D: $A(Ax_{0213}^T)_{0213}^T := \text{Einsum}(ij, b j k l \rightarrow b i k l)$
 - 184 3. Depth-wise batch IDWT 1D: $A(A(Ax_{0213}^T)_{0213}^T)_{0132}^T := \text{Einsum}(ik, b j k l \rightarrow b j i l)$
- 185 Therefore, DWT of x yield coefficients:

$$q_c := \text{DWT}(x) = [A(A(Ax_{0213}^T)_{0213}^T)_{0132}^T]_{0132}^T$$

- 186 4. Stacking for all c channels as $Q := (q_c)_{\forall c}$ to a shape (batch, height, width, depth,
187 channels).
- 188 5. Group subbands and return an output $Q^{(\text{grouped})}$ of shape (batch, height/2, width/2,
189 depth/2, $8 \times \text{channels}$).

Grouping Eight subbands in 3D DWT

mid = int(Q.shape[2]/2)

LLL = Q[:, :mid, :mid, :mid, :]

LLH = Q[:, :mid, :, :mid, :mid, :]

LHL = Q[:, :mid, mid, :, :mid, :]

LHH = Q[:, :mid, :, mid, :, :mid, :]

HLL = Q[:, :mid, :mid, mid, :, :]

HLH = Q[:, :mid, :, mid, mid, :, :]

HHL = Q[:, :mid, mid, mid, :, :]

HHH = Q[:, :mid, :, mid, :, :]

output = Concatenate([LLL, LLH, LHL, LHH, HLL, HLH, HHL, HHH], axis=-1)

190 4.2.2 IDWT 3D layer

191 An IDWT 3D layer operates on input tensors of shape (batch, height/2, width/2, depth/2, $8 \times$
192 channels) and produces an output of shape (batch, height, width, depth, channels) as de-
193 scribed in Algorithm 3b.

195 Algorithm 3b

- 196 1. Input $Q^{(\text{grouped})}$ of shape (batch, height/2, width/2, depth/2, $8 \times \text{channels}$)
- 197 2. Ungroup to get Q of shape (batch, height, width, depth, channels)
- 198 3. Generate synthesis matrix S using height, width and depth of Q .
- 199 4. For each batched channel $q_c \in Q$ of shape (batch, height, width, depth):
200 (omitting suffix c in q below for simplicity of notation)
 - 201 1. Row-wise batch IDWT 1D: $Sq_{0132}^T := \text{Einsum}(ik, b j k l \rightarrow b j i l)$

- 202 2. Column-wise batch IDWT 1D: $S(Sq_{0132}^T)_{0132} := \text{Einsum}(ij, b j k l \rightarrow b i k l)$
 203 3. Depth-wise batch IDWT 1D: $S(S(Sq_{0132}^T)_{0132}^T)_{0213}^T := \text{Einsum}(ij, b j k l \rightarrow b i k l)$
 204 or equivalently, a perfect reconstruction,

$$x_c := \text{IDWT}(q) = [S(S(Sq_{0132}^T)_{0132}^T)_{0213}^T]_{0213}^T$$

205 where, $S = A^T$ for orthogonal wavelets.

- 206 5. Layer output (perfect reconstruction): $X := (x_c)_{\forall c}$ is of shape (batch, height, width, depth, channel)

208 In general, a seamless realization of fast D-dimensional DWT and IDWT is possible by extending
 209 the above separable method to all the independent N axes one after the other. The number
 210 of subbands will be equal to 2^D for a D dimensional DWT. For example, sequences ($D = 1$)
 211 yield two subbands, images ($D = 2$) yield four subbands, three-dimensional inputs ($D = 3$)
 212 with voxels yield eight subbands etc.

213 5 Multilevel wavelet filter banks

214 The above-discussed DWT and IDWT layers are building blocks in constructing multilevel
 215 DWT filter banks. Figure 7 shows the partitioning of the 1D frequency axis and tiling of
 216 the 2D frequency plane using a level-4 1D and 2D DWT. The multilevel DWT successively
 217 decomposes the low-frequency feature. If the high-frequency features are also decomposed
 218 successively, then we get a Wavelet Packet Transform (WPT) filter bank.

Figure 7: Spatial-frequency tiling by DWT level 4 decomposition of a sequence of length N (top) and image of shape $N \times N$ (bottom).
